

Orbits of globular clusters  
can be studied using RR-Lyrae,  
which can be treated as standard  
candles, and Doppler shifts  
and similar, if more complex,  
trigonometric methods, as their  
orbits are not circular and are out of the Galactic  
disk and inclined to the Galactic disk  
~~also~~

is this relevant?

This is a very good and full account — much more  
material than required
